ABSTRACT

The present study is conducted to produce an account of the inventory of plant species, phytosociological characteristics and determination of species diversity of vegetation of Gunjan Ecological Park pit lake, West Bengal, India. Pit lakes are large water body and are generated from abandoned open mines. These pit lakes are not only large water reservoirs but also have rich floral biodiversity which could play a great role in socio-economic aspect. The vegetation of these pit lakes are also important for rehabilitation. Our principle objective of this paper is to inventory of the embankment and aquatic vegetation and determine the phytosociology and phytoclimate of the study area. Five different sites were randomly taken in various directions of the study area. A total of 50 quadrats were laid down in various directions of the study area to quantify vegetation. During our investigation, we found hundred different embankment tree species representing 41 families and 14 aquatic species of 13 families in the study site. The growth patterns, life form, life span, phytosociology and phytoclimate analysis of plant communities of the study area could reflects the ecological restoration of this region.

INTRODUCTION

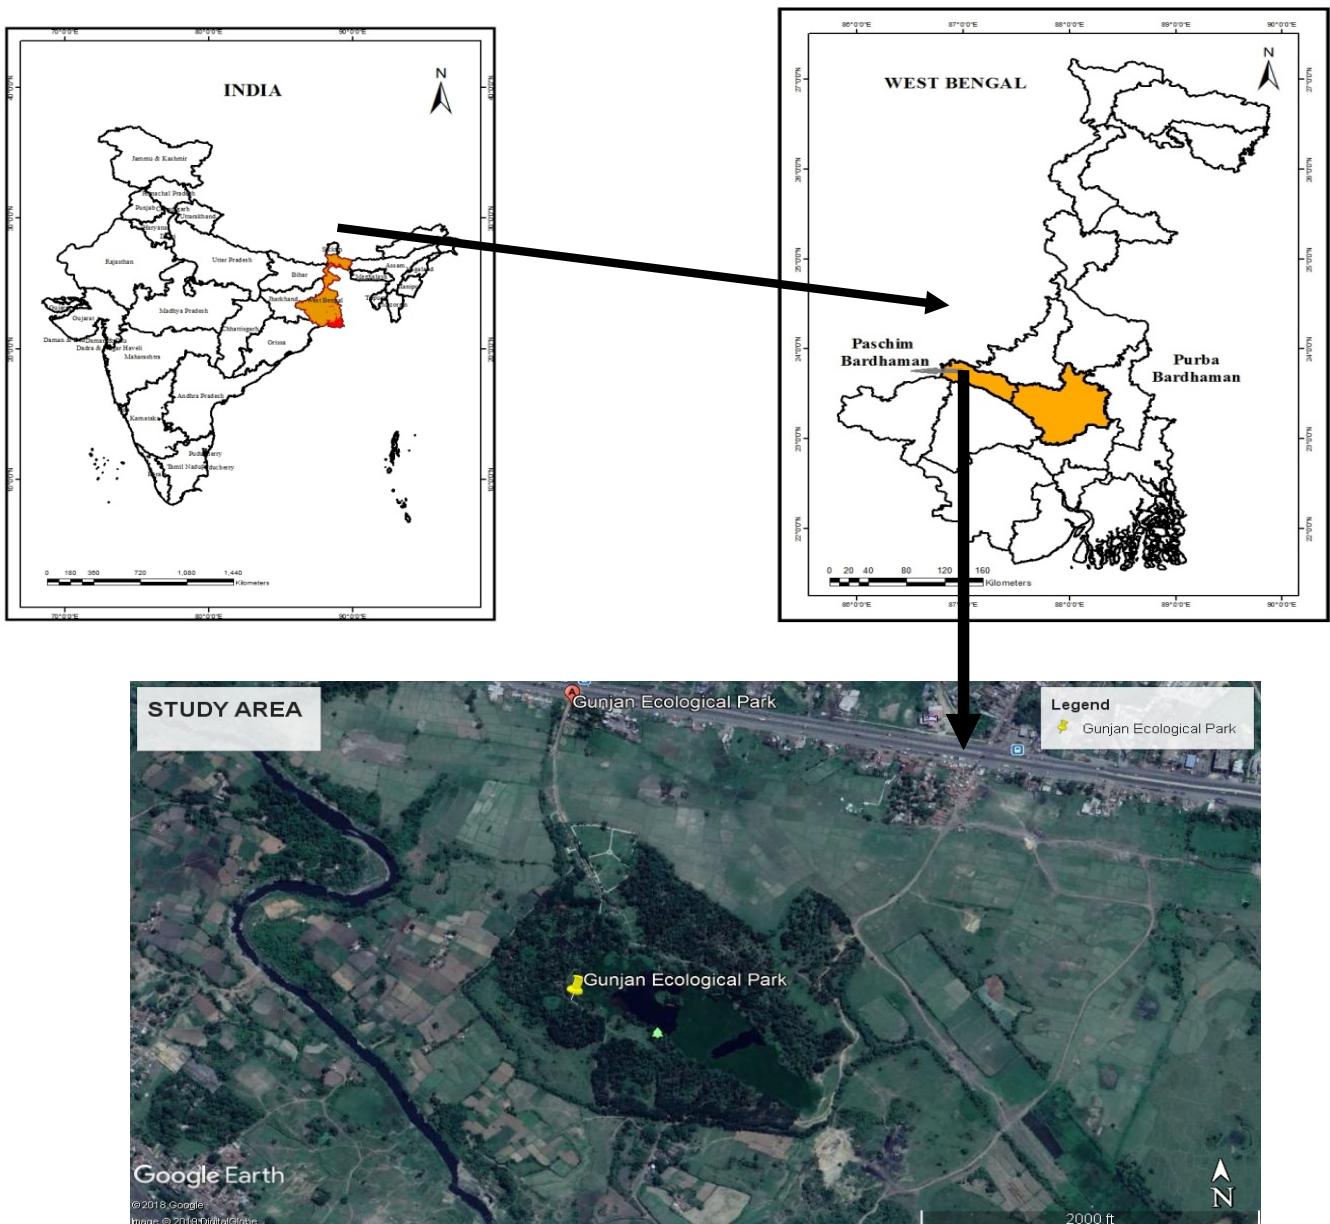

Open cast mining operation disrupts landscape pattern, disrupts indigenous flora and soil microbes. Pit lakes are generated after closing of surface mining operations and dewatering process ceases. These pits are flooded with water mainly by ground water recharge and also by side drainage. Pit lakes provide a huge source of water and have values as resources for multifarious purposes such as water supply, recreation, wildlife habitat, fisheries etc. depending on their characteristics and topography. In the context of land use and climate change, it is very useful to study the function of species richness in proper functioning of ecosystem^{1, 2}. Species richness is dependent on different types of biotic and abiotic factors^{3, 4}. The plant diversity is influenced mainly by species distribution and abundance at any site. The study has been conducted for detailed inventory and phytosociological analysis of different embankment plant species of the study area. This paper also highlights about the different available hydrophytes in the study area. The present study also deals with the determination of biological spectrum of floral assemblage of the embankment flora. The term biological spectrum was introduced to evaluate the distribution of different life forms and their respective phytoclimatic condition. A normal spectrum was made to compare the spectrum of different life forms. The obtain differences between the normal spectrum and a biological spectrum would indicate which life-form characterizes the phytoclimate of the vegetation under study. The percentage distribution of different life-forms was calculated to prepare biological spectrum of the study area and the obtain values were used to compare with the values thus determined, were compared with the Raunkiaer's normal spectrum⁵. Jaccard's Generic Coefficient⁶ which gives an indication of trend of the microclimatic status of a floristic organization was determined by the following formula: Generic Coefficient = No. of genera/No. of species x 100.

MATERIALS AND METHODS

Study area

Gunjan ecological park is located in between $23^{\circ}39'54.5''\text{N}$ and $87^{\circ}1'49.6''\text{E}$ at 94.5m elevation in Jamuria block under Asansol subdivision, West Bengal (figure 1). It is about 40 years old. Its mean depth is 70-80ft above.. Sripur is nearest village. Other village around this pitlake is Nigha. It is used for pisciculture, fishing activity; irrigation, livestock bathing, domestic purpose and fodder purpose. Conservation initiative was adopted by local Police department and they transformed this pit lake and its surroundings area into an ecological park.

Location map of the study area

Source: Google Earth

Figure 1: Location Map of the study Site

Inventory of plant species

An extensive survey of the selected study area was performed and the floral species were identified using standard literature^{7, 8}. Herbariums of different plant species were also prepared following standard literature⁹ at Dept. of Botany, Durgapur Govt. College, Durgapur, West Bengal.

Phytosociological studies

A total of 5 randomly selected sites have been taken for vegetation analysis. At each site 10 quadrats (1x1 m) were laid. Individuals of shrubs, herbs, climbers and tree seedlings were enumerated within each quadrat. The compositions of vegetation were analyzed in terms of density, relative density, frequency, relative frequency, abundance, relative abundance calculated following standard methods¹⁰. The sum basal area values were used to calculate importance value indexes (IVI) for the species were calculated using the sum of relative density, relative frequency and relative abundance. Jaccard's Generic Coefficient⁶ which gives an indication of trend of the microclimatic status of a floristic organization was determined by the following formula: Generic Coefficient = No. of genera/No. of species x 100.

The distribution pattern of the species was studied following Whit ford's index¹¹. Whit ford' s index = Abundance (A)/ Frequency (F) if A/F ratio:< 0.025 :Regular distribution; 0.025 - 0.05 :Random distribution, > 0.05 :Contagious or clumped distribution Raunkiaer frequency class analysis was performed to examine the rarity or commonness of the tree species¹². In this classification, the percentage frequency of the species was classified as A, B, C, D, and E, where A represents rare (0–20%), B represents low frequency (20–40%), C represents intermediate frequency (40–60%), D represents moderately high frequency (60–80%),and E represents high frequency or common (80–100%) (See table 3).

Diversity indices analysis

The data generated were synthesized to represent the diversity of plant species. Diversity parameters were determined using the Shannon-Weaver information function¹³. Vegetations were also measured for species richness¹⁴ and evenness ($H/\ln S$), where H means Shannon's diversity index and S represents species richness (See table 4).

Phytoclimatic study

In this study, the life-forms of 100 species recorded from the study area was determined following the system of classification of Raunkiaer and the Biological Spectra obtained accordingly⁵ (Table 5).

Statistical analysis

Correlation analysis has been performed to study the inter-relationship between phytosociological attributes.

RESULTS AND DISCUSSION

The study site deserves special mention for its floristic composition. Since, the presence of all life forms of plants is one of the characteristic features of forest and may form the bulk of the forest flora and have immense functional values, the present work keeps confined into taxonomic account of them. A summary of phytosociological data of embankment flora is summarized in table 3. The community was composed of as many as 100 species of 90 genera from 41 families of which 16 species are trees, 58 are herbs, 11 are shrubs and 15 climber species were recorded (figure 2). The study also reflects about the aquatic flora, composed of 13 families, 13 genus and 14 species (table 2). Taxonomic survey of the embankment flora reflects the dominance of dicotyledonous plants, whereas aquatic flora shows equal proportion of monocotyledonous and dicotyledonous plants (table 1 & 2).

Cry: Cryptophytes, Hc: Haemicryptophytes, Th: Helophytes, Ph: Phenerophytes, Che: Chamaephyte, M: Monocot, D: Dicot Phytosociology of vegetation community is a good indicator of ecological condition of land ecosystem. Alteration in the abiotic factors may lead to changes in the community structure in a short span of time¹⁵. Present study reflected mean density is highest in trees whereas shrubs species shows lowest value. The dominance was different for tree, shrub and herb and climbers component of the study area. In terms of importance value *Senna siamea* (IVI: 41.91) was the dominant tree species whereas *Borassus flabellifer* (IVI: 6.14) was the least dominant tree species. Among herbaceous species *Alternanthera sessilis* (IVI: 12.32) was the dominant species. In the shrub layer *Barleria prionitis* (53.54) and among the climber species, *Dioscorea alata* (IVI: 44.9) was the dominant species (table. 3).

Plant communities show three types of spatial distribution: clumped, random and regular. To understand the pattern of aggregation and dispersion of species, it is very important to know the habitat and resource utilization of the species. The distribution patterns of the species are influenced by the different physico-chemical parameters of water and soil^{16, 17, 18}. Majority of species of the study site showed random as well as clumped distribution pattern in the study sites.

D=Density, A=Abundance, F=Frequency, FC=Frequency Class, RF=Relative Frequency, RD=Relative Density,

RA=Relative Abundance, IVI=Important Value Index

The diversity indices of different embankment plants species are listed in table 4. Shannon diversity index value of tree, herbs, shrubs and climbers species are 2.537, 3.724, 1.992 and 2.149 respectively. Mean species richness value of tree, herb, shrub and climbers are 3.364, 3.247, 2.513 and 2.977 respectively, whereas, the mean evenness index of tree, herb, shrub and climbers are 0.045, 0.018, 0.067 and 0.048 respectively. The Generic Coefficient, which serves as an index of

diversification, was found to be 90%. The biological spectrum data (Table 5 & Fig.3) highlight much lower abundance of cryptophytes and much higher abundance of therophytes.

Table 5: Representation of Different Life-forms of Embankment Flora and Comparison of Obtained Biological Spectrum with Raunkiaer's Standard Spectrum of Gunjan Ecological Park Pit Lake

Life-forms	No. of species	Raunkiaer's standard	Obtained biological spectrum
Phanerophyte	31	46	31
Therophyte	46	13	46
Hemicryptophyte	09	26	9
Chamaephyte	12	9	12
Cryptophyte	02	6	2

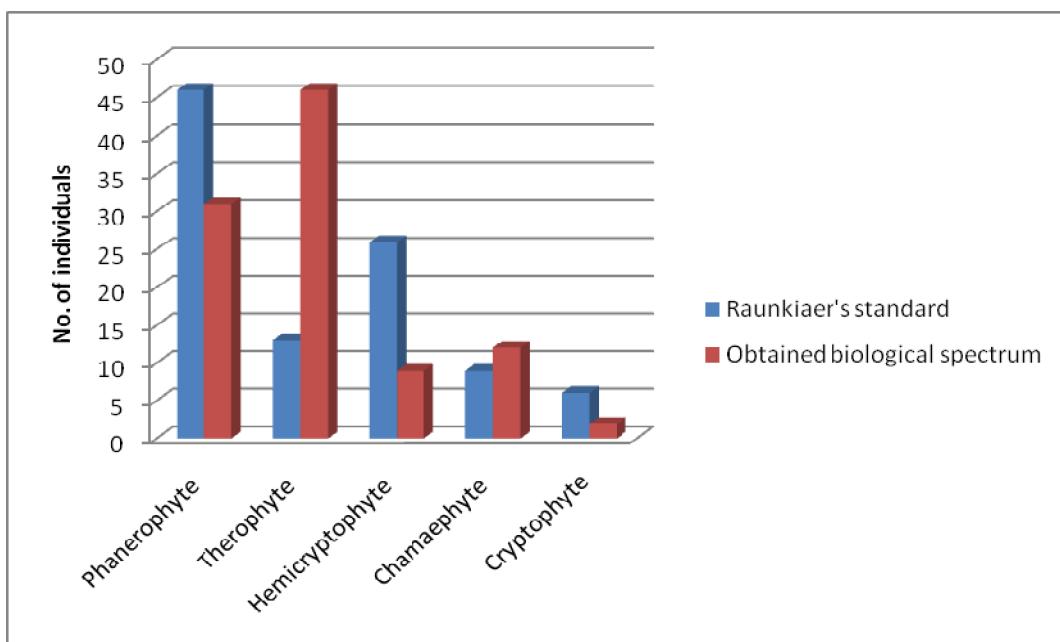

Figure 3: Graphical Representation of Different Life-forms of Embankment Flora of Gunjan Ecological Park Pit Lake

Correlation studies between different phytosociological parameters of tree species shows that density is positively correlated with frequency and IVI in case of tree, herbs, shrubs and climber species. The correlation between frequency and IVI also shows positive relation in tree, herb, shrub and climbers species (see table 6, 7, 8 & 9).
