#### ABSTRACT

Let  $G = (V, E)$  be a connected graph of order  $n$ . A set  $S \subseteq V(G)$  is called an open geodetic dominating set of  $G$  if  $S$  is both open geodetic set and dominating set of  $G$ . The minimum cardinality of an open geodetic dominating set of  $G$  is called the open geodetic domination number of  $G$  and is denoted by  $\gamma_{og}(G)$ . An open geodetic dominating set of minimum cardinality is called  $\gamma_{og}$ - set of  $G$ . An open geodetic dominating set  $S$  in a connected graph  $G$  is called a minimal open geodetic dominating set of  $G$  if no proper subset of  $S$  is an open geodetic dominating set of  $G$ . The maximum cardinality of a minimal open geodetic domination set of  $G$  is the upper open geodetic domination number of  $G$  and is denoted by  $\gamma_{og}^+(G)$ . A minimal open geodetic dominating set of cardinality  $\gamma_{og}^+(G)$  is called a  $\gamma_{og}^+$ - set of  $G$ . The upper open geodetic dominating number of certain classes of graph are determined. Some general properties satisfied by this concept are studied. For any positive integers  $a$  and  $b$  with  $2 \leq a \leq b$ , there exists a connected graph  $G$  with  $\gamma_{og}(G) = a$  and  $\gamma_{og}^+(G) = b$ .

**KEYWORDS :** Open geodetic number, Open geodetic domination number, upper open geodetic dominating number.

**AMS Subject Classification:** 05C05, 05C69.

## INTRODUCTION

By a graph  $G = (V, E)$ , we mean a finite, undirected connected graph without loops or multiple edges. The order and size of  $G$  are denoted by  $n$  and  $m$  respectively. For basic graph theoretic terminology, we refer to Harary<sup>10</sup>. The *distanced*( $u, v$ ) between two vertices  $u$  and  $v$  in a connected graph  $G$  is the length of a shortest  $u - v$  path in  $G$ . An  $u - v$  path of length  $d(u, v)$  is called an  $u - v$  *geodesic*. A vertex  $x$  is said to lie on a  $u - v$  geodesic  $P$  if  $x$  is a vertex of  $P$  including the vertices  $u$  and  $v$ . The closed interval consists of  $x, y$  and all vertices lying on some  $x - y$  geodesic of  $G$ <sup>1</sup>. For a non-empty set  $S \subseteq V(G)$ , the set  $I[S] = \bigcup_{x,y \in S} I[x, y]$  is the closure of  $S$ . A set  $S \subseteq V(G)$  is called a *geodetic set* if  $I[S] = V(G)$ . Thus every vertex of  $G$  is contained in a geodesic joining some pair of vertices in  $S$ . The minimum cardinality of a geodetic set of  $G$  is called the *geodetic number* of  $G$  and is denoted by  $g(G)$ . A geodetic set of minimum cardinality is called  $g$ -set of  $G$ <sup>2,4,5,6</sup>.  $N(v) = \{u \in V(G) : uv \in E(G)\}$  is called the *neighborhood* of the vertex  $v$  in  $G$ . A vertex  $v$  is an *extreme* vertex of a graph  $G$  if  $\langle N(v) \rangle$  is complete. A set of vertices  $D$  in a graph  $G$  is a *dominating set* if each vertex of  $G$  is dominated by some vertex of  $D$ . The *domination number*  $\gamma(G)$  of  $G$  is the minimum cardinality of a dominating set of  $G$ <sup>3,7</sup>. If  $e = \{u, v\}$  is an edge of a graph  $G$  with  $d(u) = 1$  and  $d(v) > 1$ , then we call  $e$  a *pendent edge*,  $u$  a *leaf* and  $v$  a *support* vertex. Let  $L(G)$  be the set of all leaves of a graph  $G$ . For any connected graph  $G$ , a vertex  $v \in V(G)$  is called a *cut vertex* of  $G$  if  $V - v$  is no longer connected. A set of vertices  $S$  in  $G$  is called a *geodetic dominating set* if  $S$  is both a geodetic set and a dominating set. The minimum cardinality of a geodetic dominating set of  $G$  is its *geodetic domination number* and is denoted by  $\gamma_g(G)$ . A geodetic dominating set of size  $\gamma_g(G)$  is said to be a  $\gamma_g$ -set of  $G$ <sup>9,12</sup>. A set  $S$  of vertices of a connected graph  $G$  is an *open geodetic set* if for each vertex  $v$  in  $G$  either  $v$  is an extreme vertex of  $G$  and  $v \in S$  or  $v$  is an internal vertex of a  $x - y$  geodesic for some  $x, y \in S$ . An *open geodetic set* of minimum cardinality is a minimum open geodetic set and this cardinality is the *open geodetic number* and is denoted by  $og(G)$ <sup>14</sup>. A set  $S \subseteq V(G)$  is called an *open geodetic dominating set* of a connected graph  $G$  if  $S$  is both open geodetic set and dominating set of  $G$ . The minimum cardinality of an open geodetic dominating set of  $G$  is called *open geodetic domination number* of  $G$  and is denoted by  $\gamma_{og}(G)$ <sup>13</sup>. An open geodetic dominating set of minimum cardinality is called  $\gamma_{og}$ -set of  $G$ . For a cut vertex  $v$  in a connected graph  $G$  and the component  $H$  of  $G - v$ , the subgraph  $H$  and the vertex  $v$  together with all edges joining  $v$  to  $V(H)$  is called a *branch* of  $G$  at  $v$ . The *middle graph* of a graph  $G = (V, E)$  is the graph  $M(G) = (V \cup E, E')$ , Where  $uv \in E'$  if and only if either  $u$  is a vertex of  $G$  and  $v$  is an edge of  $G$  containing  $u$ , or  $u$  and  $v$  are edges in  $G$  having a vertex in common.

The following theorem is used in sequel.

**Theorem1.1**[13]. Let  $G$  be a connected graph of order  $n$ . Then

- i. every open geodetic dominating set of a graph  $G$  contains its extreme vertices.
- ii. every end vertex belongs to every open geodetic dominating set of  $G$ .
- iii. if the set  $S$  of extreme vertices of  $G$  is an open geodetic dominating set of  $G$ , then  $S$  is the unique minimum open geodetic dominating set of  $G$  and  $\gamma_{og}(G) = |S|$ .

**THE UPPER OPEN GEODETIC DOMINATION NUMBER OF A GRAPH**

**Definition2.1.** An open geodetic dominating set  $S$  in a connected graph  $G$  is called a minimal open geodetic dominating set of  $G$  if no proper subset of  $S$  is an open geodetic dominating set of  $G$ . The maximum cardinality of a minimal open geodetic dominating set of  $G$  is the upper open geodetic domination number of  $G$  and is denoted by  $\gamma_{og}^+(G)$ . A minimal open geodetic dominating set of cardinality  $\gamma_{og}^+(G)$  is called a  $\gamma_{og}^+$ -set of  $G$ .

**Example2.2.** For the graph  $G$  given in Figure 1,  $S_1 = \{v_1, v_2, v_3, v_6, v_9\}$  and  $S_2 = \{v_1, v_2, v_3, v_5, v_7, v_9\}$  are open geodetic dominating sets of  $G$ . It is clear that no proper subsets of  $S_1$  and  $S_2$  are open geodetic dominating sets of  $G$  and so  $S_1$  and  $S_2$  are minimal open geodetic dominating sets of  $G$ . Hence  $\gamma_{og}(G) = 5$  and  $\gamma_{og}^+(G) = 6$ . It is clear that there is no minimal open geodetic dominating set of cardinality greater than 6. Therefore

Figure 1  
A graph with  $\gamma_{og}^+(G) = 6$

$\gamma_{og}^+(G) = 6$ .

**Theorem2.3.** Let  $G$  be a connected graph of order  $n$ . Then

- (i) every minimal open geodetic dominating set of a graph  $G$  contains its extreme vertices.
- (ii) every end vertex belongs to every minimal open geodetic dominating set of  $G$ .
- (iii) if  $G$  has the unique minimal open geodetic dominating set, then  $\gamma_{og}(G) = \gamma_{og}^+(G)$ .

Proof. (i) Since every minimal open geodetic dominating set of connected graph  $G$  is an open geodetic dominating set of  $G$ , by Theorem 1.1, (i) and (ii) follows immediately.

(iii) Let  $S$  be unique minimal open geodetic dominating set of a connected graph  $G$ . Then it is clear that  $\gamma_{og}(G) = |S|$  and  $\gamma_{og}^+(G) = |S|$ . Hence  $\gamma_{og}(G) = \gamma_{og}^+(G)$ .

**Theorem 2.4.** For the complete graph  $G = K_n$ ,  $\gamma_{og}^+(G) = n$ .

**Proof.** Since every vertex of  $G$  is an extreme vertex, then by Theorem 2.3(i)  $\gamma_{og}^+(G) = n$ .

**Theorem 2.5.** If a connected graph  $G$  has  $m$  extreme vertices, then  $\gamma_{og}^+(G) \geq m$ .

**Proof.** As every minimal open geodetic dominating set of a connected graph  $G$  contains its extreme vertices, by Theorem 2.3(i)  $\gamma_{og}^+(G) \geq m$ .

**Theorem 2.6.** Let  $M(G)$  be the middle graph of a connected graph  $G$  of order  $n$ .

Then  $\gamma_{og}(M(G)) = \gamma_{og}^+(M(G)) = n$ .

**Proof.** Let  $M(G)$  be the middle graph of a connected graph  $G$  of order  $n$ . Then it is clear that set of extreme vertices of  $M(G)$  is  $V(G)$ . It is easily verified that  $V(G)$  is the unique minimal open geodetic dominating set of  $M(G)$ . Therefore, by Theorem 2.3(iii)  $\gamma_{og}(M(G)) = \gamma_{og}^+(M(G)) = n$ .

**Theorem 2.7.** Let  $G$  be a connected graph of order  $n$ ,  $2 \leq \gamma_{og}(G) \leq \gamma_{og}^+(G) \leq n$ .

**Proof.** Since every open geodetic dominating set needs at least two vertices, Therefore  $\gamma_{og}(G) \geq 2$ . Since every minimal open geodetic dominating set is a open geodetic dominating set of  $G$ ,  $\gamma_{og}(G) \leq \gamma_{og}^+(G)$ . Also since the set of all vertices of  $G$  is an open

geodetic dominating set of  $G$ ,  $\gamma_{og}^+(G) \leq n$ . Hence  $2 \leq \gamma_{og}(G) \leq \gamma_{og}^+(G) \leq n$ . ■

**Remark 2.8.** The bounds in Theorem 2.7 are sharp. For the path  $G = P_2$ ,  $\gamma_{og}(G) = 2$ . For the star  $G = K_{1,n-1}$ ,  $\gamma_{og}(G) = \gamma_{og}^+(G) = n - 1$ . For the complete graph,  $G = K_n$ ,  $\gamma_{og}(G) = \gamma_{og}^+(G) = n$ . Also the bounds in Theorem 2.7 are strict. For the graph  $G$  given in Figure 2,  $\gamma_{og}(G) = 7$ ,  $\gamma_{og}^+(G) = 8$  and  $n = 11$ . Thus  $2 \leq \gamma_{og}(G) \leq \gamma_{og}^+(G) \leq n$ .

Figure 2

**Theorem 2.9.** For the connected graph  $G$   $\gamma_{og}(G) = 2$  if and only if  $\gamma_{og}^+(G) = 2$ .

**Proof.** If  $\gamma_{og}^+(G) = 2$ , then by Theorem 2.7,  $\gamma_{og}(G) = 2$ . Conversely, let  $\gamma_{og}(G) = 2$ . Then  $G$  contains two extreme vertices  $u$  and  $v$  such that  $S = \{u, v\}$  is the unique minimum  $\gamma_{og}$ -set of  $G$ .

Since  $S$  is subset of every open geodetic dominating set it follows that  $S = \{u, v\}$  is the unique minimal open geodetic dominating set of  $G$ , so that  $\gamma_{og}^+(G) = 2$ . ■

**Theorem 2.10.** Let  $G$  be a connected graph of order  $n$ . If  $\gamma_{og}(G) = n$ , if and only if

$$\gamma_{og}^+(G) = n.$$

**Proof.** If  $\gamma_{og}(G) = n$ , then by Theorem 2.7,  $\gamma_{og}^+(G) = n$ . Conversely, let  $\gamma_{og}^+(G) = n$ . Then  $S = V(G)$  is the unique minimal open geodetic dominating set of  $G$ . Hence it follows that  $S$  is the unique minimum open geodetic dominating set of  $G$ , so that  $\gamma_{og}(G) = n$ . ■

**Theorem 2.11.** Let  $G$  be a connected graph of order  $n$ . If  $\gamma_{og}(G) = n - 1$ , then  $\gamma_{og}^+(G) = n - 1$ .

**Proof.** Let  $\gamma_{og}(G) = n - 1$ . Then by Theorem 2.7,  $\gamma_{og}^+(G) = n$  or  $n - 1$ . If  $\gamma_{og}^+(G) = n$ , then by Theorem 2.10,  $\gamma_{og}(G) = n$ , Which is a contradiction. Therefore  $\gamma_{og}^+(G) = n - 1$ .

**Theorem 2.12.** For the complete Bipartite graph  $G = K_{m,n}$  with  $2 \leq m \leq n$ ,  $\gamma_{og}^+(G) = 4$ .

**Proof.** Let  $G = K_{m,n}$ . Let  $X = \{u_1, u_2, \dots, u_m\}$  and  $Y = \{v_1, v_2, \dots, v_n\}$  be the partite sets of  $G$ . Let  $S = \{u_i, u_j, v_r, v_s\}$ . Then  $S$  is a minimal open geodetic dominating set of  $G$  and so  $\gamma_{og}^+(G) \geq 4$ . We show that  $\gamma_{og}^+(G) = 4$ . If not, let  $\gamma_{og}^+(G) \geq 5$ . Then there exists a minimal open geodetic dominating set  $S'$  such that  $|S'| \geq 5$ . If  $S' \subseteq X$ , then  $S'$  is not a open geodetic dominating set of  $G$ , Which is a contradiction. If  $S' \subseteq Y$ , then  $S'$  is not a open geodetic dominating set of  $G$ , Which is a contradiction. Therefore,  $S' \subseteq X \cup Y$ . Let  $S' = S_1 \cup S_2$ , Where  $S_1 \subseteq X$  and  $S_2 \subseteq Y$ . Then  $|S_1| \geq 2$  and  $|S_2| \geq 2$ . Since  $|S'| \geq 5$ , either  $S_1$  or  $S_2$  contains atleast three vertices, without loss of generality let us assume that  $|S_1| \geq 3$ . Let  $x, y, z \in S_1$  and  $v \in S_2$ . Then  $x, y, z, u, v \in S'$ . Let  $S'' = S' - \{x\}$ , Which is a contradiction to  $S'$  is a minimal open geodetic dominating set of  $G$ . Let  $S'' = S' - \{x\}$ . Then  $S''$  is a open geodetic dominating set of  $G$  such that  $S'' \subset S'$  which is a contradiction to  $S'$  is a minimal open geodetic dominating set of  $G$ . Therefore  $\gamma_{og}^+(G) = 4$ .

**Theorem 2.13.** For any connected non-complete graph  $G$  of order  $n$ , then  $\gamma_{og}^+(G) \leq n - \delta(G)$ .

**Proof.** Let  $S$  be a upper open geodetic dominating set of a non-complete connected graph  $G$  order  $n$ . Then  $\gamma_{og}^+(G) = |S|$ . We show that  $|S| \leq n - \delta(G)$ . Let  $v \in S$ . Assume that  $v$  is adjacent to  $m$  distinct vertices in  $S$ . Since  $deg(v) > \delta(G)$ ,  $v$  must be adjacent to atleast  $\delta(G) - m$  vertices in  $V(G) - S$  and so  $|V(G) - S| > \delta(G) - m$ . If  $m = 0$ , then  $|V(G) - S| \geq \delta(G)$ , that is  $|S| \leq |V(G)| - \delta(G) = n - \delta(G)$ . If  $m > 0$ , then the  $m$  distinct vertices belong to  $N[S]$  and does not lie on a geodesic joining any pair of vertices of  $S$ , Since  $S$  is a minimal open geodetic dominating set of  $G$ ,  $|V(G) - S| \geq (\delta(G) - m) + m = \delta(G)$ . Hence  $|S| \leq n - \delta(G)$ . Therefore  $\gamma_{og}^+(G) \leq n - \delta(G)$ . ■

**Remark 2.14.** The bounds in Theorem 2.13 are sharp. For the graph  $G = K_{1,n-1}$  of order  $n$ . It is clear that  $\delta(G) = 1, n - \delta(G) = n - 1$  and  $\gamma_{og}^+(G) = n - 1$ . Thus  $\gamma_{og}^+(G) = n - \delta(G)$ . The bounds in Theorem 2.13 can be strict. For the graph  $G$  in Figure 3,  $\delta(G) = 1, \gamma_{og}^+(G) = 4, n = 6, n - \delta(G) = 5$ . Thus  $\gamma_{og}^+(G) < n - \delta(G)$ .

G  
Figure 3

**Theorem 2.15.** Let  $G$  be a connected graph of order  $n$  and  $u \in V(G)$ . If  $\deg(u) = 1$ , then  $\gamma_{og}^+(G - u) \leq \gamma_{og}^+(G)$ .

**Proof.** Let  $u \in V(G)$  and  $\deg(u) = 1$ . Let  $S$  be a minimal open geodetic dominating set of  $G - u$  with maximum cardinality, so  $\gamma_{og}^+(G - u) = |S|$ . Since  $\deg(u) = 1$ ,  $u$  is an end vertex and  $u$  is adjacent to exactly one vertex, say  $v$ . By Theorem 2.3 every minimal open geodetic dominating set of  $G$  contains  $u$ . We consider two cases.

case(i): Let  $v \in S$ . Since  $S$  is an open geodetic dominating set of  $G - u$ , there exists a vertex  $w \in V(G - u)$  such that  $w \in I[v, x] \subseteq I[S], w \in N[S], v, x \in I[S]$  and  $d(v, x) \leq 3$ . If  $d(v, x) = 3$ , then consider the set  $S' = (S - \{v\}) \cup \{u, w\}$ . If  $d(v, x) \leq 2$  then consider the set  $S' = (S - \{v\}) \cup \{u\}$ . It is straight forward to verify that  $S'$  is a minimal open geodetic dominating set of  $G$ . So that  $\gamma_{og}^+(G - u) = |S| \leq |S'| \leq \gamma_{og}^+(G)$ .

case(ii): Let  $v \notin S$ . Then consider the set  $S' = S \cup \{u\}$ . It is straight forward to verify that  $S'$  is a minimal open geodetic dominating set of  $G$ . So that  $\gamma_{og}^+(G - u) = |S| < |S'| \leq \gamma_{og}^+(G)$ . Hence in both the cases,  $\gamma_{og}^+(G - u) \leq \gamma_{og}^+(G)$ . ■

**Remark 2.16.** The bounds in Theorem 2.15 are sharp. For the graph  $G = P_4$ , let  $u$  be an end vertex of  $G$ . It is clear that  $\gamma_{og}^+(G - u) = 2$  and  $\gamma_{og}^+(G) = 2$ . Hence  $\gamma_{og}^+(G - u) = \gamma_{og}^+(G)$ . The bounds in Theorem 2.16 can be strict. For the graph  $G$  in Figure 4,  $\gamma_{og}^+(G - u) = 3$  and  $\gamma_{og}^+(G) = 4$ . Hence  $\gamma_{og}^+(G - u) < \gamma_{og}^+(G)$ .

G  
Figure 4

**Remark 2.17.** The converse of the Theorem 2.15 is need not true. For the completegraph  $K_n$ , it is clear that  $\gamma_{og}^+(K_n) = n$ ,  $\gamma_{og}^+(K_n - u) = n - 1$  and  $\deg(u) = n - 1$  forevery  $u \in V(K_n)$ . Hence  $\gamma_{og}^+(K_n - u) < \gamma_{og}^+(K_n)$  but  $\deg(u) \neq 1$ .

**Remark 2.18.** Theorem 2.15 is not true if  $\deg(u) \neq 1$ . For the graph  $G = P_5$ , givenin Figure 5,  $\gamma_{og}^+(G) = 3$ ,  $\gamma_{og}^+(G - u) = 4$  and  $\deg(u) = 2 \neq 1$ . Thus  $\gamma_{og}^+(G - u) \not\leq \gamma_{og}^+(G)$ .

G  
Figure 5

**Theorem 2.19.** For any non-trivial tree  $T$  with  $n \geq 3$ , there exists a vertex  $v \in V(T)$  such that  $\gamma_{og}^+(T - v) = \gamma_{og}^+(T)$ .

**Proof.** Let  $T$  be any non-trivial tree with  $n \geq 3$ . It can be verified that the result istrue for  $n = 3$ . Since if  $n = 3$  then  $T = P_3$ . Now consider the case that  $n > 3$ . Since  $T$  has atleast one vertex with degree greater than or equal to 2, there exists a vertex  $v \in V(T)$  with  $\deg(v) \geq 2$  such that  $v$  is adjacent to atleast one leaf and atmostone non-leaf. If there exists a vertex  $v$  such that  $v$  is adjacent to atleast one- leafand no non-leaf then it is clear that  $T = K_{1,n-1}$  and  $v$  is the support vertex So that  $\gamma_{og}^+(T - v) = n - 1 = \gamma_{og}^+(T)$ . If there does not exist a vertex  $v$  such that  $v$  is adjacentto exactly one leaf, then it is clear that  $v$  is adjacent to two or more leaves. Assumethat  $v$  is adjacent to exactly one non-leaf. By Theorem 2.3 every minimal opengeodetic dominating set of  $T$  contains its leaves So it is clear that  $\gamma_{og}^+(T - v) = \gamma_{og}^+(T)$ . If there exists a vertex  $v$  such that  $v$  is adjacent to exactly one leaf  $u$  and one non-leaf, then  $\deg(u) = 1$  and  $\deg(v) = 2$ . Let  $T' = T - v - u$ . Since  $\deg(u) = 1$ , By Theorem 2.16,  $\gamma_{og}^+(T - v) \leq \gamma_{og}^+(T)$ . Hence,  $\gamma_{og}^+(T') \leq \gamma_{og}^+(T - u) \leq \gamma_{og}^+(T)$ . However, we have  $\gamma_{og}^+(T') > \gamma_{og}^+(T) - 1$ . If  $\gamma_{og}^+(T') = \gamma_{og}^+(T) - 1$ , then  $\gamma_{og}^+(T) = \gamma_{og}^+(T - u)$ . If  $\gamma_{og}^+(T') > \gamma_{og}^+(T) - 1$ , then

$\gamma_{og}^+(T') = \gamma_{og}^+(T) = \gamma_{og}^+(T - u)$ . Hence there exists a vertex  $v \in V(T)$  such that  $\gamma_{og}^+(T - v) = \gamma_{og}^+(T)$ . ■

**Remark 2.20.** Theorem 2.19 is not true for any graph  $G$ . For the complete graph  $K_n$ ,

$$\gamma_{og}^+(K_n - v) \neq \gamma_{og}^+(K_n) \text{ for every } v \in V(K_n).$$

**Theorem 2.21.** Let  $G$  be a connected graph of order  $n$ . If  $G'$  is a graph obtained by adding  $k$ , where  $1 \leq k \leq n$ , end edges to a graph  $G$ , then  $\gamma_{og}^+(G) \leq \gamma_{og}^+(G') \leq \gamma_{og}^+(G) + k$ .

**Proof.** Let  $G$  be a connected graph of order  $n$  and let  $G'$  be a connected graph obtained from  $G$  by adding  $k$  end edges  $u_i v_i$  ( $1 \leq i \leq k$ ), where each  $u_i \in V(G)$  and  $v_i \notin V(G)$ . First we show that  $\gamma_{og}^+(G) \leq \gamma_{og}^+(G')$ . Let  $S$  be a  $\gamma_{og}^+$ -set of  $G$ , so  $\gamma_{og}^+(G) = |S|$ . We now consider three cases.

**Case(i):** Let  $u_i \in S$  for all  $i$  ( $1 \leq i \leq k$ ). Then let  $S' = S \cup \{v_1, v_2, \dots, v_k\}$ . Since each

$v_i \notin V(G)$  is an end vertex of  $G'$  and  $u_i \notin S, v_i \notin I[S]$  and  $v_i \notin N[S]$ ,  $S'$  is a minimal

open geodetic dominating set of  $G'$ . Therefore  $\gamma_{og}^+(G) = |S| < |S'| \leq \gamma_{og}^+(G')$ .

**Case(ii):** Let  $u_i \in S$  for some  $i, 1 \leq i \leq k$ . Since  $S$  is an open geodetic dominating set of  $G$ , there exists a vertex  $v \notin S$  such that  $v \in I[u_i, x] \subseteq I[S], v \in N[S]$  and  $d(u_i, x) \leq 3$  for some  $x \in S$ . If  $d(u_i, x) = 3$ , then consider the set  $S' = (S - \{u_i\}) \cup \{v_i, v\}$ . If  $d(u_i, x) \leq 2$ , then consider the set  $S' = (S - \{u_i\}) \cup \{v_i\}$ . It is easily verified that  $S'$  is a minimal open geodetic dominating set of  $G'$ . Therefore  $\gamma_{og}^+(G) = |S| \leq |S'| \leq \gamma_{og}^+(G')$ .

**Case(iii):** Let  $u_i \notin S$  for all  $i, 1 \leq i \leq k$ . Then by the similar argument as in case(ii),

we can prove that  $\gamma_{og}^+(G) \leq \gamma_{og}^+(G')$ . Next, we show that  $\gamma_{og}^+(G') \leq \gamma_{og}^+(G) + k$ . Let  $S \subseteq V(G)$  and let  $S' = S \cup \{v_1, v_2, \dots, v_k\}$  be a minimal open geodetic dominating set of  $G'$  with maximum cardinality so that  $\gamma_{og}^+(G') = |S'| = |S| + k$ . Since  $S'$  is a minimal open geodetic dominating set of  $G', u_i \notin S$  for all  $i$ , where  $1 \leq i \leq k$ . We show that  $S$  is a minimal open geodetic dominating set of  $G$ . If not, then there exists a vertex  $u_i \in V(G) - S$  such that  $u_i \notin I[S]$  or  $u_i \notin N[S]$ . Then the set  $S \cup \{u_i\}$  ( $1 \leq i \leq k$ ) is a minimal open geodetic dominating set of  $G$ . Hence  $\gamma_{og}^+(G') = |S| + k \leq \gamma_{og}^+(G) + k$ .

**Theorem 2.22.** For any two integer  $a$  and  $n$  with  $2 \leq a \leq n$ , there exists a connected graph  $G$  with  $\gamma_{og}^+(G) = a$  and  $|V(G)| = n$ .

**Proof.** It can be easily verified that the result is true for  $2 \leq n \leq 3$ . If  $n = 2$ , then  $G = K_2$

and if  $n = 3$ , then  $G$  is either  $P_3$  or  $K_3$ . For  $n \geq 4$ . If  $a = n$ , then  $G = K_n$  and if  $a = n - 1$ , then  $G = K_{1, n-1}$ . For  $a \leq n - 2$ . Let  $P: x, y, z$  be a path on three vertices. Let  $G$  be a graph obtained from  $P$  by adding new vertices  $z_1, z_2, \dots, z_{a-3}, v_1, v_2, \dots, v_{n-a}$  and joining each  $z_i$  ( $1 \leq i \leq a - 3$ ) with  $z$ , and

joining each  $v_i$  ( $1 \leq i \leq n - a$ ) with  $x$  and  $z$ . The graph  $G$  is shown in Figure 6. Let  $S = \{z_1, z_2, \dots, z_{a-3}\}$ . Then By Theorem 1.1 (i)  $S$  is a subset of every open geodetic dominating set. It is easily verified that  $S \cup \{u\}$ , and  $S \cup \{u, v\}$  is not an open geodetic dominating set of  $G$  and so  $\gamma_{og}^+(G) \geq a$ . Now  $S' = S \cup \{x\} \cup \{y, v_i\}$  ( $1 \leq i \leq n - a$ ) or  $S' = S \cup \{x\} \cup \{v_i, v_j\}$  ( $1 \leq i, j \leq n - a$ ) is a minimal open geodetic dominating set of  $G$  and so  $\gamma_{og}^+(G) \geq a$ . We prove that  $\gamma_{og}^+(G) = a$ . If not, suppose that  $\gamma_{og}^+(G) > a$ . Then there exists a minimal open geodetic dominating set of  $S''$  with  $|S''| \geq a + 1$ . Then  $S''$  contains at least two  $v_i$  ( $1 \leq i \leq n - a$ ). Now  $v_i$  must lie on  $I[x, z_j]$  for ( $1 \leq i \leq n - a$ ) and ( $1 \leq j \leq a - 3$ ). Then  $x$  must belong to  $S''$ . Then it follows that  $S' \subset S''$ , which is a contradiction to  $S''$  is a minimal open geodetic dominating set of  $G$ . Therefore  $\gamma_{og}^+(G) = a$ .

**Theorem 2.23.** For any two integer  $a$  and  $b$  with  $2 \leq a \leq b$ , there exists a connected graph  $G$  with  $\gamma_{og}(G) = a, \gamma_{og}^+(G) = b$ .

**Proof.** It can be easily verified that the result is true for  $2 = a = b$ . Consider the graph  $G = K_n$ . It is clear that  $\gamma_{og}(K_2) = 2, \gamma_{og}^+(K_2) = 2$ . If  $2 < a = b$ , then consider the graph  $G = K_n$  ( $n > 2$ ). It is clear that  $\gamma_{og}(K_n) = \gamma_{og}^+(K_n) = n$ . If  $2 < a = b$ , then consider the graph  $G = K_{1,n}$ . It is clear that  $\gamma_{og}(K_{1,n}) = \gamma_{og}^+(K_{1,n}) = n - 1$ . Now we consider  $2 < a < b$ . Let  $P: x, u, v, w, t$  be a path on five vertices. Let  $H$  be a graph obtained from  $P$  by adding new vertices  $z_1, z_2, \dots, z_{a-4}$  and joining each  $z_i$  ( $1 \leq i \leq a - 4$ ) with  $u$ . Let  $G$  be a graph obtained from  $H$  by adding new vertices  $y, s, v_1, v_2, \dots, v_{b-a+1}$  and joining each  $v_i$  ( $1 \leq i \leq b - a + 1$ ) with  $x$  and  $y$  and joint  $s$  with  $y$  and  $t$ , the graph  $G$  is shown in Figure 7. First we show that  $\gamma_{og}(G) = a$ . Let  $Z = \{z_1, z_2, \dots, z_{a-4}\}$  be the set of all endvertices of  $G$ . By Theorem 1.1 (i)  $Z$  is a subset of every open geodetic dominating set of  $G$ . It is easily verified

that  $Z$  is not a open geodetic dominating set of  $G$ . It is easily verified that  $Z \cup \{x_1\}$  or  $Z \cup \{x_1, x_2\}$  or  $Z \cup \{x_1, x_2, x_3\}$  is not a open geodetic dominating set where  $x_1, x_2, x_3 \notin Z$  and so  $\gamma_{og}(G) \geq a$ . Now  $S = Z \cup \{y, s, w, u\}$  is an open geodetic dominating set of  $G$  so that  $\gamma_{og}(G) = a$ . Next we prove that  $\gamma_{og}^+(G) = b$ . Let  $W = Z \cup \{v_1, v_2, \dots, v_{b-a+1}, s, t, u\}$ . Then  $W$  is an open geodetic dominating set of  $G$  and so  $\gamma_{og}^+(G) \geq a - 4 + b - a + 1 + 3 = b$ . First we prove that  $W$  is a minimal open geodetic dominating set of  $G$ . Suppose that  $W$  is not a minimal open geodetic dominating set of  $G$ . Then there exists  $W' \subset W$  such that  $W'$  is a open geodetic dominating set of  $G$ . Hence there exists  $z \in W$  such that  $z \notin W'$ . By Theorem 1.1 (ii)  $z \neq z_i (1 \leq i \leq a - 4)$ . If  $z = v_i (1 \leq i \leq b - a + 1)$  then  $W'$  is not a dominating set of  $G$ . If  $z = s$  or  $t$  or  $u$ , then  $W'$  is not an open geodetic set of  $G$ . Hence  $W'$  is not an open geodetic dominating set of  $G$ . Therefore  $W$  is a minimal open geodetic dominating set of  $G$ . Next we prove that  $\gamma_{og}^+(G) = b$ . Suppose that  $\gamma_{og}^+(G) \geq b + 1$ . Then there exists a open geodetic dominating set of  $T$  such that  $|T| \geq b + 1$ . By Theorem 1.1(i)  $Z \subset T$ . Suppose that  $v_i \notin T$  for some  $i$ . Then  $s \in T$  and either  $v$  or  $w \in T$ . Let us assume that  $v \in T$ . Now  $s$  and  $v$  must lie on some pair of vertices of  $T$ . Which implies  $t$  must belongs to  $T$ . Hence  $T$  contains open geodetic dominating set, which is a contradiction. Therefore  $\gamma_{og}^+(G) = b$ . ■
