Role of Artificial Intelligence in Hospitals: How it has changed the Healthcare system

Dhoundiyal Neha¹, Yadav Neha², Sharma Prerna³, Savaria Mukesh^{4*} & Singh Neha⁵

Master's in Hospital Management at Delhi Pharmaceutical Sciences and Research University, New Delhi¹, Senior Process Associate, TCS, Virar Homoeopathic Medical College, Virar, Maharashtra², Master's in Public Health at DPSRU, New Delhi³, Assistant Research Officer, THE INCLIN TRUST INTERNATIONAL^{4,*}, Research scholar at DPSRU, New Delhi, India⁵

ABSTRACT

Due to the increasing complexity of medical procedures Artificial intelligence is gaining popularity in healthcare. This paper provides an overview about the use of AI in hospitals as in IPD, ICU, Data support, Patient management and logistics, etc. After assessing inclusion and exclusion criteria out of initially identified 78 articles, a referential and cross-referential analysis of 59 articles was done for final synthesis; statistical reports are taken from McKinsey, Accenture and Statista. Reports from Niti Ayog on Current scenario of AI in India, initiative of government, future Objective and Aim were considered. Insights of wearable, sensors, neural technique, accelerometer, fuzzy logic and other aspect of AI are discussed in detail. Successful working model of AI-PPP in Indian hospitals like MINE, NIRMAI, DRISHTI are highlighted. Result reveals an exponential growth of AI in hospital's ecosystem however identifies the gap in requirement for future researches, issues in technology acceptance, data security and lack of legal framework.

KEYWORDS: Artificial intelligence, Patient management, Data support, Data Security

1. INTRODUCTION

Healthcare service industry especially hospitals are facing unprecedented pressure in recent times due to changing demographics of the population, expanding administrative burden, need of more skilled workforce, rapidly changing pattern of morbidity along with increasing demand and expectations of the individuals. All these pressure points can be easily dealt with by the introduction of artificial intelligence in the hospital system. Artificial intelligence along with it forms like machine learning is being increasingly used in the healthcare industry due to its potential to transform the management, care, and satisfaction of patient in the hospital set up. Artificial intelligence not only have the capability of easing out the patient aspect within hospital set up but also helps in various other domain like administrative process, inventory management, internal patient department, and intensive care units.

Various studies have been done then and now have repeatedly suggested the precise performance of artificial intelligence-powered technology in various health care branches whether diagnostic or administrator.

In 2016 the artificial industry has the largest share of investment when compared to any other sector in the global economy¹. Artificial intelligent aims to mimic human cognitive functions. AI provides a positive shift in hospital management due to its analytical technique. Artificial intelligence is used in fields like detection and diagnosis of disease, predicting the treatment and its outcome and decision-making².

2. TYPES OF AI USED IN HOSPITALS-

2.1. Machine learning

This can be explained as the statistical process of assessing data to learn, train and interpret a specific model with the help of this data, commonest forms of artificial intelligence that is used in hospitals¹³. Among healthcare industry, the most common use of machine learning is predictive technology which is most famous due to its precision¹⁴.

2.2. Neural system network

A complex technological technique machine learning which was released in 1960¹⁵. It has been used to predict the disease prevalence and pattern within patients. This is done by analyzing input-output based on patient details like weight and history.

2.3. Deep learning

This is yet another famous form of machine learning which is being rapidly used in different fields of healthcare. This is specifically being used in recent years for disease diagnostic says through

radiological aid like cancer lesion¹⁶. Technology aided deep learning can find the smallest of information through data imaging detection which can be skipped by a human eye specially in case of rare cancers¹⁷. This is known as computer-aided detection or CAD.

2.4. Natural language processing

This technology is based on sensing, understanding and analyzing human languages. There are two basic approaches through which natural language processing helps the healthcare industry that is semantic and statistical within the hospital ecosystem Natural language processing can be used in creating, understanding and classifying the tons of clinical data received on daily basis¹³.

2.5. Robots

An artificial intelligence-powered robot has been in the US since 2000. They have the capability of assisting surgeons by improving ability for precise, low invasive incisions and better stitch wound management in surgeries¹⁸. They are capable of performing tasks like delivering supplies, managing inventory and maintenance support in hospitals as mentioned in

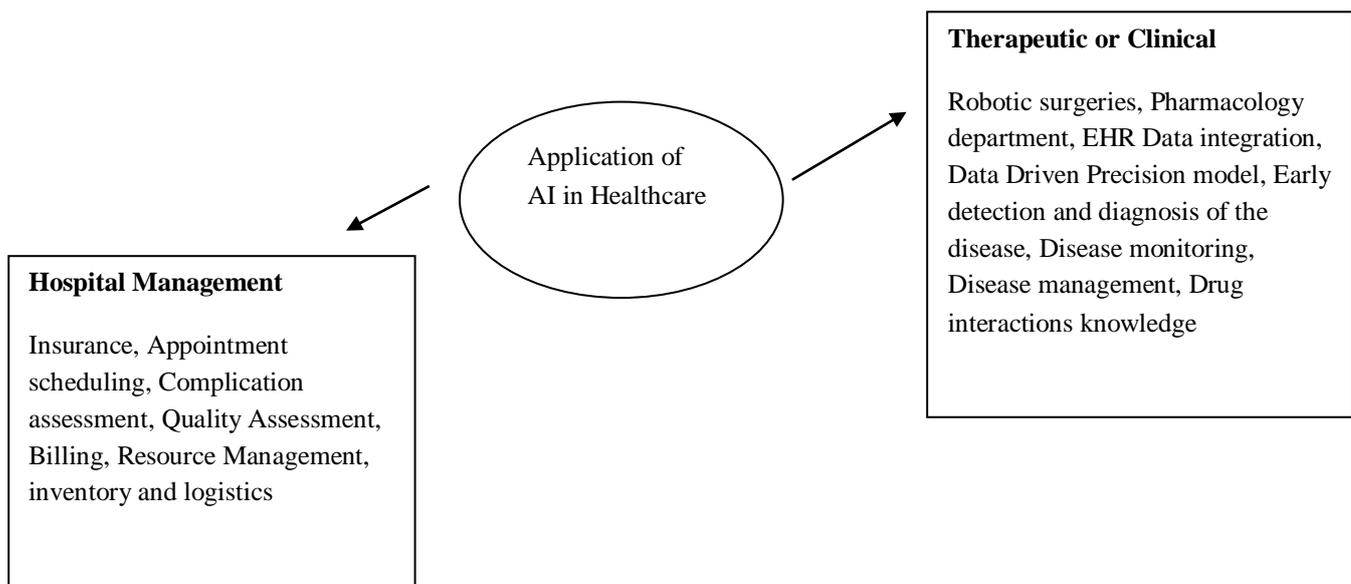

Figure 1: Use of AI in health sector

3. USE OF AI IN HOSPITALS

AI is used for mostly the three usual tasks involved in clinical practices of the hospital that are the diagnosis, prognosis, and therapy³⁹. Generally, the medical diagnosis cycle in any disease may include observation and examination, patient data, formulating a diagnosis. If we can compare the medical diagnostic cycle to the concept of an intelligent agent system, the physician is the intelligent agent, the patient data is the input and the diagnosis is the output. The practical application of this systematic approach can be seen in Clinical Decision Support Systems (CDSS)³⁹. It is helpful in assessment of individual cases on basis of data⁵⁹.

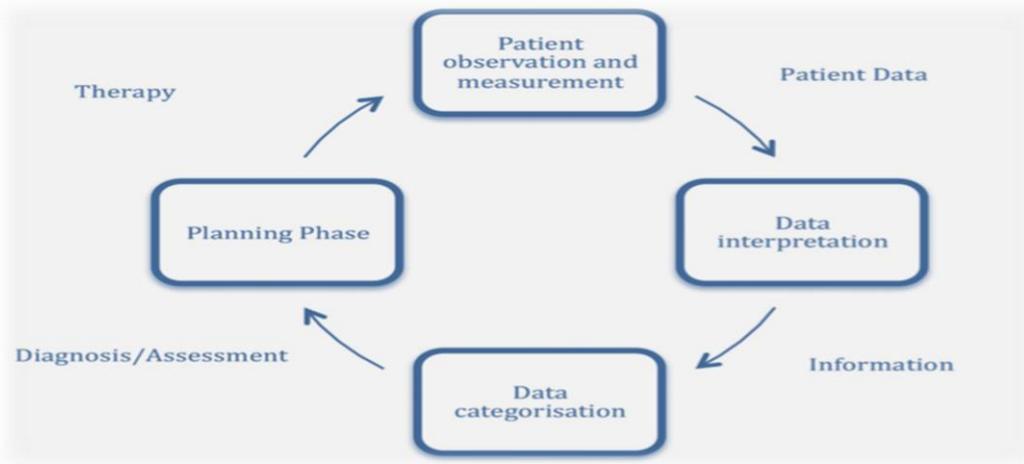

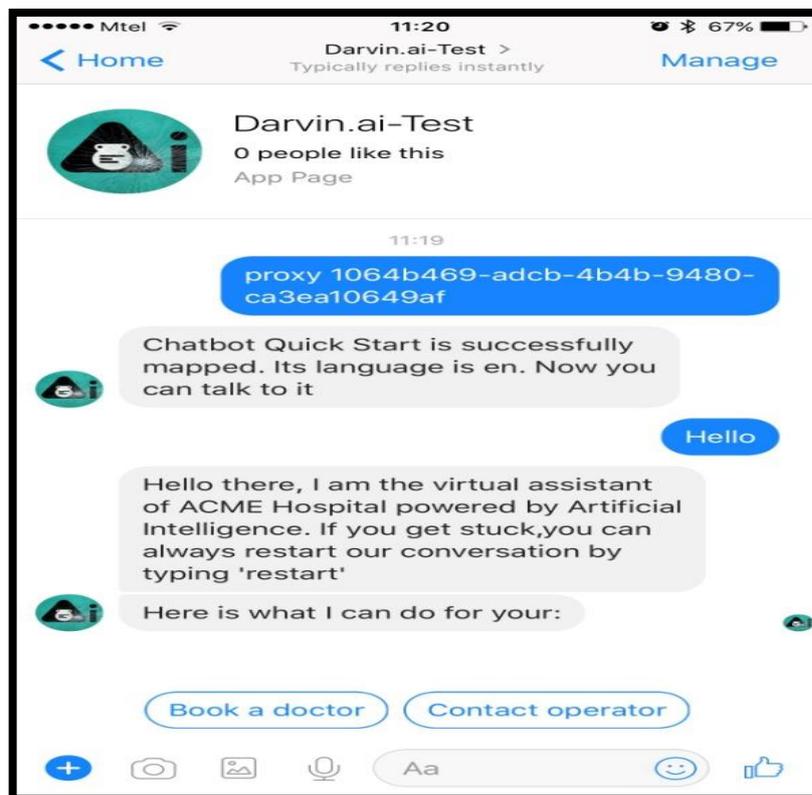

Figure 2: Patient management cycle model in artificial intelligence

Screenshot – I - from an automated chat bot app that uses natural language processing to answer questions by patients to answer related to their hospital. The chat bot uses natural language processing to classify intents and respond appropriately. He is also able to recognize from a previous question.

3.1 Administration support

In recent years there has been an immense increase in the utilization of artificial intelligence and power technology in the field of health care³. The delivery system of the healthcare industry especially hospitals has become complex due to the maximum stretch capability and capacity of hospitals specifically in developing nations³. Artificial intelligence tools have been used in past and demonstrate the power to enhance the functioning of hospitals by reducing the administrative burden through augmented critical data analysis which further aims at reducing the non-clinical overload over the physician⁴.

AI techniques can help hospitals in the following method-

- a. The machine learning algorithm can be used for clinic appointment scheduling as well as patient privatization this reduces the wastage of time and enhances the efficiency of services⁵.
- b. Natural language processing, (NLP) works on voice capture and Transcription can be used to compile the notes for the Electronic medical record (EMR) hence clinicians can get more time for the patient-related process⁶.
- c. Various healthcare organizations also using AI-powered chat boxes for interactions with their patient in the field of telemedicine and mental health. This can be done through NLP based applications that are useful for refilling previously instructed prescriptions¹³. However, the use of chat bots is in very invasion stage and in and so the patient has expressed concern about security concern and poor usability¹⁹.
- d. Machine learning and AI technology can be used for matching data across various platforms and sources which is, in turn, helps in payment and claims settlement. This reduces the burden over the hospital due to the endless long claim settlement process. It also helps in analyzing the coding process which is the most common cause of incorrect claim information. It also helps in auditing through the potential use of data mining and data matching.
- e. The integration of big data helps in providing opportunities in simplifying healthcare information which is beneficial for patients, regulatory bodies and hospitals²¹.
- f. In view of Figure 2., It can be said that artificial intelligence helps in simplifying the hospital system of working be it front lines like reception or appointment scheduling or blackened working like supply chains.

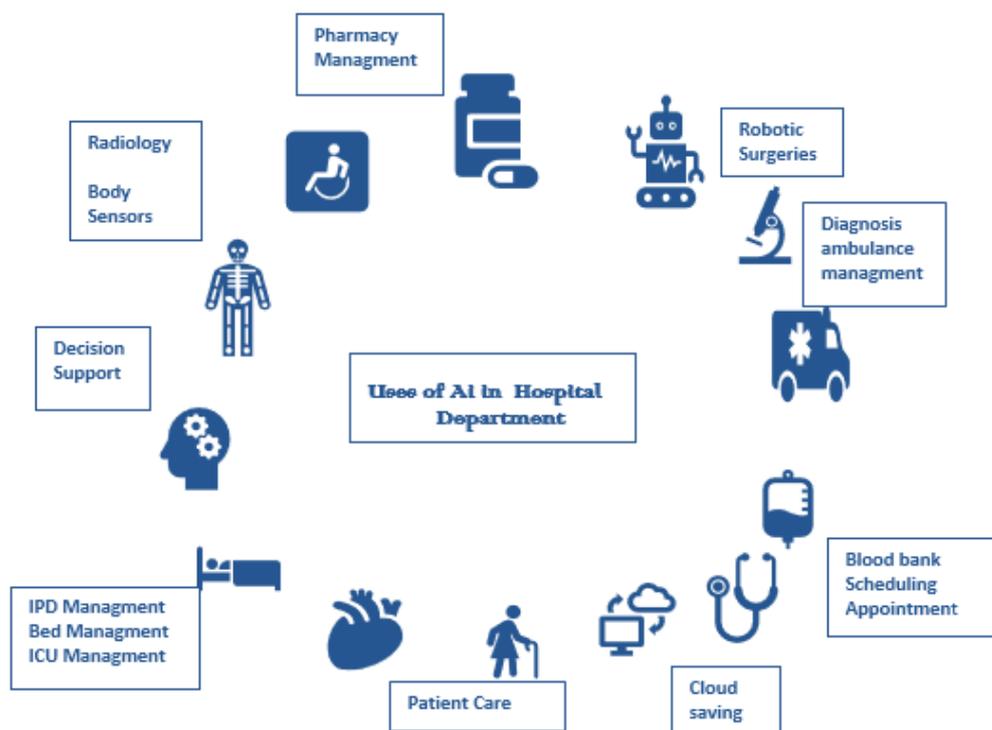

Figure 3: How use of AI is simplifies various day to day aspect of Hospital system of working

3.2 Patient management

- a. Artificial intelligence program which has been linked with the servers of hospital or self-capable of analyzing already recorded data of patient which can intern use for answering the queries of a patient. This reduces the waiting time over the counters. This also very well reduces the load over the emergency department⁷.
- b. Machine learning and AI programs which are synchronized with electronic medical records from detect patient information through their biometrics and recommend early-stage clinical guidelines⁸. This helps in better patient management even in cases of shortage of skilled manpower.
- c. AI programs can be used in administering drugs through fuzzy logic. Fuzzy logic is the logic that is based on several values procured from past experiences⁸. It is the science of reasoning, thinking which is further translated into a matter of degree. In fuzzy logic the output can be depicted as “IF” and the outcome in the form of “THEN” as mentioned in Table 1²³. For example, fuzzy logic can be used to administer vasodilator to post-operative patients.

Table 1: Typical Fuzzy Logic Information

IF	Change in bowel habit	OR	Rectal
	Bleeding		
THEN	Consult Doctor		

3.3 Better IPD bed regulation

Artificial intelligence can be used to manage the flow of patients by predicting the patient flow within the hospital system. This can be done through various uses of technologies like cloud integration, chatbots, and web-based software^{9, 10}. This is done through an intelligent patient flow management system (IFPM).

Better resource management and IPD ward utilization allow the optimal flow of patient and designated surgery planning which promises higher revenues and patient satisfaction. The integration of big data helps in providing an opportunity for both patients and the Hospital¹¹. This can be associated with the use of a potentially enhanced clinical workflow system in hospitals.

BOX: 1

Potential Enhanced Clinical Workflow with Artificial Intelligence (AI) Interventions²⁴

In a traditional system of treating the patients, the decision for treatment protocol is based on multiple factors like clinical sign and symptoms presentations, histo-pathological reports, radiological reports, blood reports, etc.

The clinical outcome is decided after a long period. In comparison to this, AI-based interventions have the potential to augment the clinical workflow to uplift the decision-making power at different stages of care. This can be further improved with the help of Continuous feedback as well as optimization from various outcomes.

3.4 In ICU settings

AI in critical care units is being used to reduce the burden on the nurses and duty doctors. This is done by optimizing workload settings. These allow clinicians and nurses to spend more time on patients rather than doing technical and paperwork. AI allows penetration of human decisions with the aid of machine learning. This puts forwards a cost-effective and highly efficient machinery system¹². Following are the tools which are being used-

- a. Variables like light sensors, head position reading, facial expression capturing are assessed with the help of video monitoring, sound sensors, and accelerometer. These technologies are converting conventional intensive care unit into an ICU information system¹² as mentioned in Figure 3(a)¹². In figure 4(a) we can see how a video screen can be seen for the scrutiny of the patient status on one hand and the other hand light sensor sound sensor and accelerometers are linked with physiological signs and symptoms which are in turn trained to work on their

own. This allows better time as well as resources management where nurses do not have to keep a visit or check again and again and utilize the same amount of time for other crucial activities.

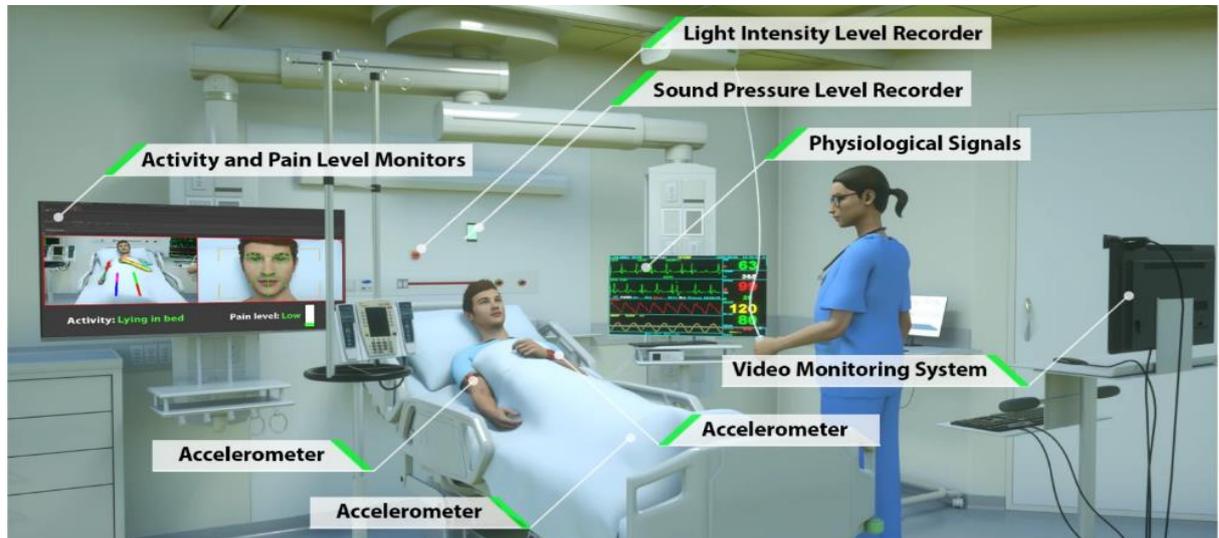

Figure 4 (a): ICU information system powered by AI: use of sensor, accelerometer and monitoring through the video are the key components of the setting. An automated technological supported ICU setting

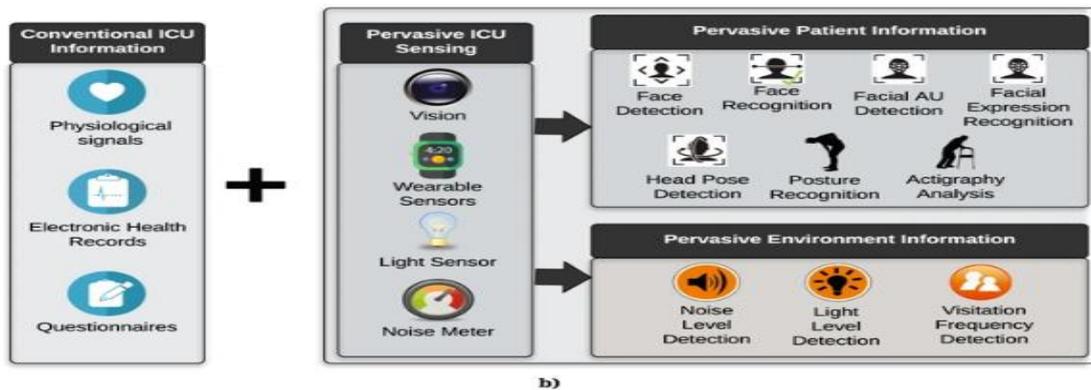

Figure 4 (b): shows how conventional ICU information are combined with AI pervasive ICU sensing
 b. Intelligent ICU used for autonomous patient monitoring using pervasive sensing and machine learning¹² Fig 4(b) shows how conventional ICU information like physiological signals, electronic health records are combined with AI pervasive ICU sensing like wearable sensors, light sensors, etc. for better patient management¹².

3.5 Inventory management and supply chain:

The use of technology can increase the efficacy of supply chains significantly. This holds well, especially for perishable items²⁰, One such example is the utilization of RFID (radio frequency identification device)²¹. AI through RFID can control the circulation of counterfeit drugs that further influence the pricing decision of materials like drugs and instruments or types of equipment²².

The use of AI can be used for analyzing expiry dates through tagging of medicines allowing early detection of expiry dates, stock management, etc. It also increases the permeability of information flow between the parties in the supply chain of the hospital like investors, stakeholders, manufacturers, wholesalers, and suppliers.

3.6 Controlling hospital acquired infection-

Hospital-acquired infection is one of the commonest complications as well as challenges in front of the hospital industry. The computerized patient records in hospitals can allow automated identification to find out the early sign of hospital-acquired infection. This can be done with the help of fuzzy logic at the ICU settings done in accordance to the European Surveillance System HELICS this is currently being in operation at the Vienna General Hospital. It is helpful in controlling infection from catheterization³⁰.

4. MATERIALS AND METHODS USED

A detailed literature review was carried, which includes searching and evaluating the cyberspace platforms like Research Gate, PubMed and Google Scholar for articles related to the topic. Articles focusing on the performance of Artificial Intelligence in hospitals since 2000 have been considered. Global and national articles published presenting the role of AI in public and private domains were studied for the eligibility and appropriateness of the topic. Multiple aspects of Total 59 articles have been considered, out of which 37 comprises of implementation model of AI in hospital (IPD, Administration, Patient flow management system) while the rest of the 09 articles were on the challenges of AI, 4 article reports the future and current scenario of AI. 4 studies deal with the therapeutic aspect of AI in Cancer, Dermatology, Vascular neurology and strokes. 5 studies focus on the standardized strategy model of India in AI. Articles have been studied for the deep understanding of AI in hospitals globally as well in the Indian context.

6. DISCUSSION

The techniques implementation of AI across hospital with current, future out-coming and actual challenges are overviewed. Analysis reveals successful AI models currently in use as Fussy logic mentioned by Ramesh A et al.⁸, Baldwin K.⁶; smart ICU System by Davoudi A et al.,¹², De Bruin J et al.,³⁰; patient Management by Jiang F et al.,², Jones S¹⁰ et al., H T. IOS Press Ebooks⁹, Neill D et al.,⁵⁸; Resource planning as described by Yousefi M et al.,⁷,Huang J et al.,⁵; Supply Chain found in Davenport T et al.,¹⁸, Utermohlen K et al.,¹⁹, Hossein P et al.,²⁰, Deniz B et al.,²² and Data integration by Ribeiro M et al.,²⁵, Gambhir S et al.,³, Yousefi M et al.,⁷, Ribeiro M et al.,²⁵, Joshi R et al.,⁴⁶. Explicit contribution of AI in cancer detection as mentioned in Farookh R et al.,¹⁶, Snyder C et

al.,⁴ Hosny A et al.,²⁴, Alanna V et al.,¹⁷, Esteva A et al.,²⁶ is observed, however acceptance among doctors, more strict regulations, data privacy, system efficiency are the key determinant of the future success and huge challenge as supported by various studies of Char D²⁸ et al., Kelly C et al.,²⁹, Hosny A et al.,²⁴, Coiera E et al.,⁴⁰, Giuliano et al.,⁴⁹.

Initiative of Indian healthcare sector came out to be appreciable but require higher degree of commitment as Indian healthcare system is unstructured and complex.

7. CONCLUSION

Literature analysis revealed despite being a significant key to the appropriate revolution in healthcare AI still lacks a widespread adoption in hospitals. There are multiple aspects of AI implementations that need to be addressed. Cost and lack of the structure came forward as the biggest challenge of AI whereas no stringent law for data privacy and leakage is major concern. Although there is huge complimenting ability of AI to health workers if implemented with sheer will but need of further researches cannot be denied specially in Indian healthcare system.
